SECURITY

⚠ CRITICAL

CREDENTIAL STUFFING WAVE

Tens of thousands of login attempts are flooding your platform using leaked passwords from a third-party breach. Real accounts are being compromised in real time. Support tickets are piling up faster than the team can respond.

Credential stuffing exploits the fact that most people reuse passwords. Attackers buy leaked credential databases and automate login attempts at scale. Defences include: rate limiting and CAPTCHA on auth endpoints, anomaly detection on login patterns, enforced MFA, breach password detection (checking new passwords against known-leaked datasets via services like HaveIBeenPwned), and fast account-lock flows. None of these are difficult to implement — but all of them must be in place before the attack, not during it. A team with a mature DevSecOps practice will have these controls automated, tested, and alerting continuously.

Users reuse passwords. You can't stop that. But you can stop the damage — if you built the right defences early.

TEAM DISCUSSION

Do you have rate limiting, anomaly detection, and MFA enforcement in place — or did security wait for later?
