SECURITY

⚠ CRITICAL

INSIDER THREAT DETECTED

Anomalous access patterns have been flagged. It appears a current or recently departed employee has been accessing and exfiltrating sensitive customer records over the past two weeks. Legal has been notified.

Insider threats — whether malicious or negligent — are disproportionately damaging because insiders already have legitimate access. The DevOps controls that limit exposure are: least-privilege access (every person and service has only the access they need and nothing more), regular access reviews (quarterly audits of who has access to what), immutable and centralised audit logs (so any access is traceable and tamper-evident), and strict offboarding checklists (credentials, tokens, and SSH keys revoked on the employee's last day, not their last week). Zero Trust architecture assumes breach and verifies every access request regardless of network location.

Not all threats come from outside. Least-privilege access, audit logs, and offboarding procedures exist for exactly this moment.

TEAM DISCUSSION

Are access rights reviewed regularly? Are departing employee credentials revoked immediately on their last day?
